To whom it may concern,

I am writing to submit a manuscript titled *Quality of Service Anomaly Detection in Wildfire Monitoring Networks* for consideration to the *Remote Sensing*. This article focuses on development and characterization of a novel method to evaluate visual anomalies impacing the ability of ALERTCalifornia cameras to monitor for natural hazards. This method comprises both a heuristic for human reviewers to evaluate the imagery with, as well as a new ML model architecture that fits this task.

This material has not been previously published.
